

MUSIC AND MENTAL HEALTH

Context of the work

- ▶ Music therapy, or MT, is the use of music to improve an individual's stress, mood, and overall mental health. MT is also recognized as an evidence-based practice, using music as a catalyst for "happy" hormones such as oxytocin.
- ▶ However, MT employs a wide range of different genres, varying from one organization to the next.
- ▶ The **MxMH** dataset aims to identify what, if any, correlations exist between an individual's music taste and their self-reported mental health.
- ▶ Ideally, these findings could contribute to a more informed application of MT or simply provide interesting insights about the mind.

Hours Spent on Music and Mental Health

Conclusions

- ❑ The analysis of the MxMH dataset uncovers specific correlations between music preferences, streaming habits, and mental health conditions, offering targeted insights for music therapy.
- ❑ Notably, users of Pandora report lower levels of depression, anxiety, insomnia, and OCD compared to those using Spotify and Apple Music, where higher levels of anxiety and depression are prevalent.
- ❑ Additionally, genres like Gospel and Classical are associated with lower anxiety, depression and OCD scores, while Lofi is linked to higher levels of depression, insomnia and OCD.
- ❑ There is no significant relationship between the hours spent on music per day and the level of the four types of mental health issues based on the r value and r -squared value calculated.
- ❑ These findings emphasize the importance of personalized music therapy that takes into account the type of music and streaming service, enabling more effective treatments and innovative approaches within the music therapy industry.

A man in a dark suit and tie is shown in profile, looking to the left with his hand resting on his chin in a thoughtful pose. The background is a solid blue color with several white question marks of varying sizes scattered throughout. A small yellow square is located in the top right corner of the image.
